The slumping may attribute to engineering excavation, which can disturb the thermal balance of the slope soil and cause thawing. However, when the summer monsoon is stronger than expected, floods can devastate the region. The underlying cause of these phenomena may be related to thawing permafrost which supplemented water to the landslide mass at points E and F Figure 22 which are exterior to the lateral edge of the slope at point ZK2.

Water generated from melting snow, precipitation, and permafrost melting. Low confidence was expressed elsewhere due to disagreement between different projections, resulting both from different models and from different indices of drought. This NASA conducted interview quickly explains what permafrost is, and what it means for Alaskan infrastructure.
